Clemson University

Notes

One-Way ANOVA & Overall F-Test

- We use **one-way ANOVA** to compare means of **J** (≥ 3) **groups/conditions**

$$H_0 : \mu_1 = \mu_2 = \dots = \mu_J$$

$$H_a : \text{at least a pair } \mu\text{'s differ}$$

- If H_0 is rejected, ANOVA just states that there is a significant difference between the groups **but not where those differences occur**
- We need to perform additional post hoc tests, **multiple comparisons**, to determine where the group differences are

Notes

Pairwise T-Tests

- Suppose we have 4 groups, i.e. $J = 4$, then we need to perform $\binom{4}{2} = 6$ two-sample tests to locate where the group differences are

$$H_0 : \mu_1 = \mu_2 \text{ vs. } H_a : \mu_1 \neq \mu_2$$

$$H_0 : \mu_1 = \mu_3 \text{ vs. } H_a : \mu_1 \neq \mu_3$$

$$H_0 : \mu_1 = \mu_4 \text{ vs. } H_a : \mu_1 \neq \mu_4$$

$$H_0 : \mu_2 = \mu_3 \text{ vs. } H_a : \mu_2 \neq \mu_3$$

$$H_0 : \mu_2 = \mu_4 \text{ vs. } H_a : \mu_2 \neq \mu_4$$

$$H_0 : \mu_3 = \mu_4 \text{ vs. } H_a : \mu_3 \neq \mu_4$$

- What if we simply perform these tests using, say, $\alpha = 0.05$ for each test?
 $\mathbb{P}(\text{making a least one type I error}) = 1 - (1 - 0.05)^6 = 0.265$
if each test was independent

Notes

Family-Wise Error Rate (FWER)

Family-Wise Error Rate (FWER) $\bar{\alpha}$: the probability of making 1 or more type I errors in a set of hypothesis tests

For m independent tests, each with individual type I error rate α , then we have

$$\bar{\alpha} = 1 - (1 - \alpha)^m$$

| m | α | | |
|-----|----------|-------|-------|
| | 0.1 | 0.05 | 0.01 |
| 1 | 0.100 | 0.050 | 0.010 |
| 3 | 0.271 | 0.143 | 0.030 |
| 6 | 0.469 | 0.265 | 0.059 |
| 10 | 0.651 | 0.401 | 0.096 |
| 15 | 0.794 | 0.537 | 0.140 |
| 21 | 0.891 | 0.659 | 0.190 |

Multiple Comparisons and Linear Contrasts

CLEMSON UNIVERSITY

16.4

Notes

The Bonferroni Correction

If we would like to control the FWER to be α , then we adjust the significant level for each of the m tests to be $\frac{\alpha}{m}$

$$FWER = \mathbb{P}(\cup_{i=1}^m p_i \leq \frac{\alpha}{m}) \leq \sum_{i=1}^m \mathbb{P}(p_i \leq \frac{\alpha}{m}) = m \frac{\alpha}{m} = \alpha$$

where p_i is the p-value for the i_{th} test
If we have 4 treatment groups, then we need to perform 6 tests ($m = 6$) \Rightarrow will need to set the significant level for each individual pairwise t-test to be $0.05/6 = 0.0083$ to ensure that FWER is less than 0.05

Remark: Bonferroni procedure can be very conservative but gives guaranteed control over FWER at the risk of reducing statistical power. Does not assume independence of the comparisons.

Notes

Me and the significant boys

Me and the significant boys after Bonferroni correction

Multiple Comparisons and Linear Contrasts

CLEMSON UNIVERSITY

16.6

Notes

Example

A researcher who studies sleep is interested in the effects of ethanol on sleep time. She gets a sample of 20 rats and gives each an injection having a particular concentration of ethanol per body weight. There are 4 treatment groups, with 5 rats per treatment. She records Rapid eye movement (REM) sleep time for each rat over a 24-period.

| Treatment | Control | 1g/kg | 2g/kg | 4g/kg |
|-----------|---------|-------|-------|-------|
| Mean | 82.2 | 81.0 | 73.8 | 65.7 |
| Std | 9.6 | 5.3 | 9.4 | 7.9 |

Recall in last lecture we reject $H_0 : \mu_1 = \mu_2 = \mu_3 = \mu_4$ at 0.05 level. But where these differences are?

Notes

Example: Multiple Testing with Bonferroni Correction

P-value

| Test | μ_1, μ_2 | μ_1, μ_3 | μ_1, μ_4 | μ_2, μ_3 | μ_2, μ_4 | μ_3, μ_4 |
|------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Pooled | 0.816 | 0.202 | 0.018 | 0.175 | 0.007 | 0.179 |
| Non-pooled | 0.818 | 0.202 | 0.019 | 0.185 | 0.009 | 0.180 |

Notes

Fisher's Protected Least Significant Difference (LSD) Procedure

- We conclude that μ_i and μ_j differ at α significance level if $|\bar{X}_i - \bar{X}_j| > LSD$, where

$$LSD = t_{\alpha/2, df=N-J} \sqrt{MSE \left(\frac{1}{n_i} + \frac{1}{n_j} \right)}$$

- This procedure builds on the equal variances t-test of the difference between two means
- The test statistic is improved by using MSE rather than s_p^2

Notes

Tukey's Honest Significance Difference (HSD) Test

- The test procedure:
 - Requires equal sample size n per populations
 - Find a critical value ω as follows:

$$\omega = q_{\alpha}(J, N - J) \sqrt{\frac{MSE}{n}}$$

where $q_{\alpha}(J, N - J)$ can be obtained from the studentized range table

- If $\bar{X}_{max} - \bar{X}_{min} > \omega \Rightarrow$ there is sufficient evidence to conclude that $\mu_{max} > \mu_{min}$
- Repeat this procedure for each pair of samples. Rank the means if possible

Notes

Facebook Friends Example

A researcher would like to investigate the relationship between Facebook social attractiveness and the number of Facebook friends. An experiment was conducted where five groups of participant judge the same Facebook profiles, except for the one aspect that was manipulated: the number of friends for that profile.

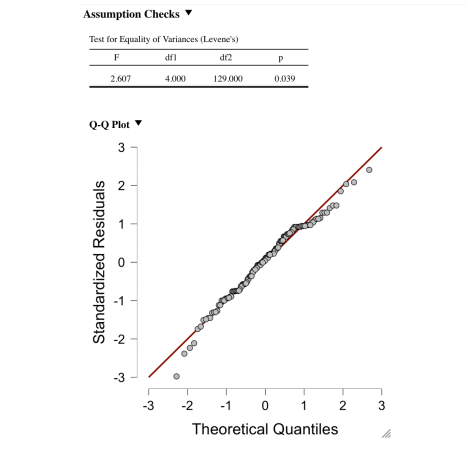

Notes

Example: Descriptive Statistics

| | Score | | | | |
|----------------|-------|-------|-------|-------|-------|
| | 102 | 302 | 502 | 702 | 902 |
| Valid | 24 | 33 | 26 | 30 | 21 |
| Missing | 0 | 0 | 0 | 0 | 0 |
| Mean | 3.817 | 4.879 | 4.562 | 4.407 | 3.990 |
| Std. Deviation | 0.999 | 0.851 | 1.070 | 1.428 | 1.023 |
| Minimum | 2.200 | 2.600 | 2.000 | 1.000 | 1.600 |
| Maximum | 6.000 | 6.400 | 6.800 | 7.000 | 5.200 |

Notes

Example: Checking Model Assumptions

Multiple Comparisons and Linear Contrasts

CLEMSON UNIVERSITY

16.13

Notes

Facebook Friends: Overall F-Test

Question: Are Facebook attractiveness affected by # of friends?

$H_0: \mu_1 = \mu_2 = \dots = \mu_5$
 H_a : At least one group mean is different from others

Analysis of Variance Table

Response: Score

| | Df | Sum Sq | Mean Sq | F value |
|-----------|-----|--------|---------|---------|
| Friends | 4 | 19.89 | 4.9726 | 4.142 |
| Residuals | 129 | 154.87 | 1.2005 | |

Pr(>F)

| | | |
|-----------|---------|----|
| Friends | 0.00344 | ** |
| Residuals | | |

Next, we need to figure out where these differences occur

Multiple Comparisons and Linear Contrasts

CLEMSON UNIVERSITY

16.14

Notes

Facebook Example: Fisher's LSD

We conclude that μ_i and μ_j differ at α level if $|\bar{X}_i - \bar{X}_j| > LSD$, where

$$LSD = t_{\alpha/2, df=N-J} \sqrt{MSE \left(\frac{1}{n_i} + \frac{1}{n_j} \right)}$$

| | | | |
|--------------------|----------|-------------------|-----------------|
| > LSD_none\$groups | | > LSD_bon\$groups | |
| Score groups | | Score groups | |
| 302 | 4.878788 | a | 302 4.878788 a |
| 502 | 4.561538 | ab | 502 4.561538 ab |
| 702 | 4.406667 | abc | 702 4.406667 ab |
| 902 | 3.990476 | bc | 902 3.990476 b |
| 102 | 3.816667 | c | 102 3.816667 b |

Multiple Comparisons and Linear Contrasts

CLEMSON UNIVERSITY

16.15

Notes

Facebook Example: Tukey's HSD Test

Yet there is another method to deal with multiple testing: **Tukey's Honest Significant Difference (HSD) test**. We conclude that μ_i and μ_j differ at α **familywise level** if $|\bar{X}_i - \bar{X}_j| > \omega$, where

$$\omega = q_\alpha(J, N - J) \sqrt{\frac{\text{MSE}}{n}},$$

$q_{\alpha}(J, N - J)$ can be obtained from the [studentized range table](#)

| Denominator | | Number of Groups (k) (a.k.a. Treatments) | | | | | | | | | |
|-------------|-------|--|-------|-------|-------|-------|-------|-------|-------|----|----|
| DF | | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 12 | 15 |
| 1 | 3.414 | 3.756 | 3.918 | 4.187 | 4.304 | 4.469 | 4.609 | 4.736 | 4.877 | | |
| 2 | 3.412 | 3.753 | 3.996 | 4.184 | 4.337 | 4.465 | 4.586 | 4.730 | 4.877 | | |
| 3 | 3.410 | 3.751 | 3.994 | 4.181 | 4.334 | 4.462 | 4.577 | 4.727 | 4.869 | | |
| 4 | 3.408 | 3.749 | 3.991 | 4.178 | 4.331 | 4.459 | 4.569 | 4.666 | 4.766 | | |
| 5 | 3.406 | 3.746 | 3.989 | 4.175 | 4.328 | 4.455 | 4.565 | 4.662 | 4.762 | | |
| 6 | 3.405 | 3.745 | 3.986 | 4.173 | 4.325 | 4.452 | 4.562 | 4.662 | 4.659 | | |
| 7 | 3.403 | 3.743 | 3.984 | 4.170 | 4.322 | 4.449 | 4.559 | 4.658 | | | |
| 8 | 3.402 | 3.741 | 3.982 | 4.168 | 4.319 | 4.447 | 4.556 | 4.652 | | | |
| 9 | 3.400 | 3.739 | 3.979 | 4.165 | 4.316 | 4.444 | 4.553 | 4.649 | | | |
| 10 | 3.399 | 3.737 | 3.977 | 4.163 | 4.314 | 4.441 | 4.550 | 4.646 | | | |

Notes

Notes

Linear Contrasts

Suppose we have J populations (e.g. response for J different treatments) of interest. We have seen how to perform multiple comparisons. For example, the comparison between μ_1 and μ_2 can be conducted using the test: $H_0: \mu_1 - \mu_2 = 0$ vs. $H_a: \mu_1 - \mu_2 \neq 0$. This comparison is actually a special case of **linear contrasts**

Linear Contrasts

Let c_1, c_2, \dots, c_J are constants where $\sum_{j=1}^J c_j = 0$, then $\sum_{j=1}^J c_j \mu_j$ is called a **linear contrast** of the population means.

Example: Suppose $J = 4$

⑦ $\mu_1 - \mu_3 : c_1 = 1, c_2 = 0, c_3 = -1, c_4 = 0$

② $\mu_2 - \mu_4 : c_1 = 0, c_2 = 1, c_3 = 0, c_4 = -1$

8 $\mu_1 - \frac{1}{3}\mu_2 - \frac{1}{3}\mu_3 - \frac{1}{3}\mu_4 : c_1 = 1, c_2 = c_3 = c_4 = -\frac{1}{3}$

Notes

Inferences for Linear Contrasts

If we want to make an inference about $L = \sum_{j=1}^J c_j \mu_j$. Then we use

$$\hat{L} = \sum_{j=1}^J c_j \bar{X}_j$$

as the point estimate. Furthermore, we can construct a $100(1 - \alpha)\%$ CI for L :

$$(\hat{L} - t_{(\alpha/2, df=N-J)} \hat{se}_{\hat{L}}, \hat{L} + t_{(\alpha/2, df=N-J)} \hat{se}_{\hat{L}}),$$

where $\hat{se}_{\hat{L}} = \sqrt{\text{MSE} \left(\frac{c_1^2}{n_1} + \dots + \frac{c_J^2}{n_J} \right)}$

To test whether L is significantly different from 0, we can conduct the following test:

$$H_0 : \sum_{j=1}^J c_j \mu_j = 0 \text{ vs. } H_a : \sum_{j=1}^J c_j \mu_j \neq 0$$

Notes

Hypothesis Testing for Linear Contrasts

- Null and Alternative Hypotheses:

$$H_0 : \sum_{j=1}^J c_j \mu_j = 0 \text{ vs. } H_a : \sum_{j=1}^J c_j \mu_j \neq 0$$

- Test Statistic:

$$t_{obs} = \frac{\hat{L} - 0}{\hat{se}_{\hat{L}}} = \frac{\sum_{j=1}^J c_j \bar{X}_j}{\sqrt{\text{MSE} \left(\frac{c_1^2}{n_1} + \dots + \frac{c_J^2}{n_J} \right)}}$$

- Decision:

Reject H_0 if $|t_{obs}| > t_{\alpha/2, df=N-J}$ (or p-value $< \alpha$)

Notes

Facebook Example: Linear Contrast

Suppose we'd like to compare μ_1 vs. $\frac{\mu_3 + \mu_4}{2}$. Let $L = 1\mu_1 - \frac{1}{2}\mu_3 - \frac{1}{2}\mu_4$. Then the above comparison is equivalent to test whether L is different from 0

- $H_0 : L = 0$ vs. $H_a : L \neq 0$

$$t_{obs} = \frac{\hat{L}}{\hat{se}_{\hat{L}}} = \frac{1 \times 3.817 - 0.5 \times 4.562 - 0.5 \times 4.407}{\sqrt{1.2005 \times \left(\frac{1^2}{24} + \frac{0.5^2}{26} + \frac{0.5^2}{30} \right)}} = \frac{-0.6674}{0.2675} = -2.495$$

- Since $|t_{obs}| = |-2.495| = 2.495 > t_{0.025, df=129} = 1.9785$. We reject H_0 at 0.05 level

Note: If we are performing several tests for different linear contrasts simultaneously, we'll need to adjust α level accordingly to control the FWER

Notes
