Multiple Linear Regression: Estimation and Inference

Reading: Faraway, 2014 Chapters 2.1 - 2.6, 3.1 - 3.2; 3.5; JWHT Chapter 3.1 - 3.2

DSA 8020 Statistical Methods II

Whitney Huang Clemson University

Agenda

Multiple Linear Regression: Estimation and Inference

Regression

Estimation & Inference

Assessing Model Fit

Multiple Linear Regression

2 Estimation & Inference

Goal: To model the relationship between two or more predictors (x's) and a response (Y) by fitting a **linear equation** to observed data:

$$y_i = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_{p-1} x_{p-1} + \varepsilon_i, \quad \varepsilon_i \stackrel{i.i.d.}{\sim} N(0, \sigma^2)$$

Example: Species diversity on the Galapagos Islands. We are interested in studying the relationship between the number of plant species (Species) and the following geographic variables: Area, Elevation, Nearest, Scruz, Adjacent.

Multiple Linear Regression: Estimation and Inference

Regression

Multiple Linear Regression: Estimation and Inference

Regression

MLR Topics

Similar to SLR, we will discuss

- Estimation
- Inference
- Diagnostics and Remedies

We will also discuss some new topics

- Model Selection
- Multicollinearity

Multiple Linear Regression: Estimation and Inference

Regression

$$\begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} = \begin{pmatrix} 1 & x_{1,1} & x_{2,1} & \cdots & x_{p-1,1} \\ 1 & x_{1,2} & x_{2,2} & \cdots & x_{p-1,2} \\ \vdots & \cdots & \ddots & \vdots & \vdots \\ 1 & x_{1,n} & x_{2,n} & \cdots & x_{p-1,n} \end{pmatrix} \begin{pmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_{p-1} \end{pmatrix} + \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \vdots \\ \varepsilon_n \end{pmatrix}$$

It will be more convenient to put this in a matrix representation as:

$$y$$
 = $Xeta$ + $arepsilon$

Error Sum of Squares (SSE) = $\sum_{i=1}^{n} \left(y_i - \left(\beta_0 + \sum_{j=1}^{p-1} \beta_j x_j\right)\right)^2$ can be expressed as:

$$(y - X\beta)^T (y - X\beta)$$

Next, we are going to find $\hat{\beta} = (\hat{\beta}_0, \hat{\beta}_1, \cdots, \hat{\beta}_{p-1})$ to minimize SSE as our estimate for $\beta = (\beta_0, \beta_1, \cdots, \beta_{p-1})$

Multiple Linear Regression: Estimation and

Regression

The resulting least squares estimate is

$$\hat{\boldsymbol{\beta}} = \left(\boldsymbol{X}^T \boldsymbol{X}\right)^{-1} \boldsymbol{X}^T \boldsymbol{y}$$

(see LS_MLR.pdf for the derivation)

Fitted values:

$$\hat{y} = X\hat{\beta} = X(X^TX)^{-1}X^Ty = Hy$$

Residuals:

$$e = y - \hat{y} = (I - H)y$$

Multiple Linear Regression: Estimation and Inference

Regression

Estimation a interence

Estimation of σ^2

Similar as we did in SLR

$$\hat{\sigma}^{2} = \frac{e^{T}e}{n-p}$$

$$= \frac{(y - X\hat{\beta})^{T}(y - X\hat{\beta})}{n-p}$$

$$= \frac{SSE}{n-p}$$

$$= MSE$$

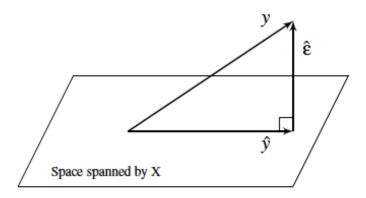

Multiple Linear Regression: Estimation and Inference

Regression

Estimation a interence

Partitioning Sums of Squares

Total sums of squares in response

$$SST = \sum_{i=1}^{n} (y_i - \bar{y})^2$$

We can rewrite SST as

$$\sum_{i=1}^{n} (y_i - \bar{y})^2 = \sum_{i=1}^{n} (y_i - \hat{y}_i + \hat{y}_i - \bar{y})^2$$

$$= \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 + \sum_{i=1}^{n} (\hat{y}_i - \bar{y})^2$$
"Error": SSE Model: SSR

Multiple Linear Regression: Estimation and Inference

regression

2.19

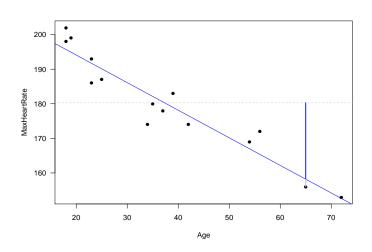

Partitioning Total Sums of Squares: A Graphical Illustration

Regression

Estimation & Inference

To answer the question: Is there a relationship between the response and predictors?

Source	df	SS	MS	F Value
Model	p-1	SSR	MSR = SSR/(p-1)	MSR/MSE
Error	n-p	SSE	MSE = SSE/(n-p)	
Total	n-1	SST		

• F-Test: Tests if the predictors $\{x_1, \dots, x_{p-1}\}$ collectively help explain the variation in Y

•
$$H_0: \beta_1 = \beta_2 = \dots = \beta_{p-1} = 0$$

•
$$H_a$$
: at least one $\beta_k \neq 0$, $1 \leq k \leq p-1$

$$\bullet \ F^* = \frac{\text{MSR}}{\text{MSE}} = \frac{\text{SSR}/(p-1)}{\text{SSE}/(n-p)} \overset{H_0}{\sim} F_{p-1,n-p}$$

• Reject
$$H_0$$
 if $F^* > F_{1-\alpha,p-1,n-p}$

- We can show that $\hat{\boldsymbol{\beta}} \sim N_p \left(\boldsymbol{\beta}, \sigma^2 \left(\boldsymbol{X}^T \boldsymbol{X}\right)^{-1}\right) \Rightarrow$ $\hat{\beta}_k \sim N(\beta_k, \sigma_{\hat{\beta}_k}^2)$
- Perform t-test:
 - $H_0: \beta_k = 0$ vs. $H_a: \beta_k \neq 0$
 - $\bullet \quad \frac{\hat{\beta}_k \beta_k}{\hat{SE}(\hat{\beta}_k)} \sim t_{n-p} \Rightarrow t^* = \frac{\hat{\beta}_k}{\hat{SE}(\hat{\beta}_k)} \stackrel{H_0}{\sim} t_{n-p}$
 - Reject H_0 if $|t^*| > t_{1-\alpha/2} |_{n-n}$
- Confidence interval for β_k:

$$\hat{\beta}_k \pm t_{1-\alpha/2,n-p} \hat{SE}(\hat{\beta}_k)$$

Regression
Estimation & Inference

Assessing Model Fit

ullet Coefficient of determination R^2 describes proportional of the variance in the response variable that is predictable from the predictors

$$R^2 = \frac{\text{SSR}}{\text{SST}} = 1 - \frac{\text{SSE}}{\text{SSR}}, \quad 0 \le R^2 \le 1$$

- ullet R^2 increases with the increasing p, the number of the predictors
 - Adjusted R^2 , denoted by $R^2_{\rm adj} = \frac{{\rm SSR}/(n-p)}{{\rm SST}/(n-1)}$ attempts to account for p

Suppose the true relationship between response Y and predictors (x_1, x_2) is

$$Y = 5 + 2x_1 + \varepsilon,$$

where $\varepsilon \sim N(0, 1)$ and x_1 and x_2 are independent to each other. Let's fit the following two models to the "data"

Model 1:
$$Y = \beta_0 + \beta_1 x_1 + \varepsilon^1$$

Model 2:
$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \varepsilon^2$$

Question: Which model will "win" in terms of R^2 ?
